Page 1/8

**Command:** as - assembler

**AS----**ASSEMBLER [IBM]

This document describes the language accepted by the 80386 assembler that is part of the Amsterdam Compiler Kit. Note that only the syntax is described, only a few 386 instructions are shown as examples.

#### **Tokens, Numbers, Character Constants, and Strings**

The syntax of numbers is the same as in C. The constants 32, 040, and 0x20 all represent the same number, but are written in decimal, octal, and hex, respectively. The rules for character constants and strings are also the same as in C. For example, 'a' is a character constant. A typical string is "string". Expressions may be formed with C operators, but must use [ and ] for parentheses. (Normal parentheses are claimed by the operand syntax.)

#### **Symbols**

Symbols contain letters and digits, as well as three special characters: dot, tilde, and underscore. The first character may not be a digit or tilde.

The names of the 80386 registers are reserved. These are:

```
al, bl, cl, dl
ah, bh, ch, dh
ax, bx, cx, dx, eax, ebx, ecx, edx
si, di, bp, sp, esi, edi, ebp, esp
cs, ds, ss, es, fs, gs
```

The xx and exx variants of the eight general registers are treated as synonyms by the assembler. Normally "ax" is the 16-bit low half of the 32-bit "eax" register. The assembler determines if a 16 or 32 bit operation is meant solely by looking at the instruction or the instruction prefixes. It is however best to use the proper registers when writing assembly to not confuse those who read the code.

The last group of 6 segment registers are used for selector + offset mode addressing, in which the effective address is at a given offset in one of the 6 segments.

Names of instructions and pseudo-ops are not reserved. Alphabetic characters in opcodes and pseudo-ops must be in lower case.

#### **Separators**

Sep 03, 14 11:21

MAN\_AS.TXT

Page 2/8

Commas, blanks, and tabs are separators and can be interspersed freely between tokens, but not within tokens. Commas are only legal between operands.

#### **Comments**

The comment character is '!'. The rest of the line is ignored.

#### **Opcodes**

The opcodes are listed below. Notes: (1) Different names for the same instruction are separated by '/'. (2) Square brackets ([]) indicate that 0 or 1 of the enclosed characters can be included. (3) Curly brackets ({} ) work similarly, except that one of the enclosed characters must be included. Thus square brackets indicate an option, whereas curly brackets indicate that a choice must be made.

#### **Data Transfer**

```
mov[b] dest, source ! Move word/byte from source to dest
pop dest ! Pop stack
push source ! Push stack
xchg[b] op1, op2 ! Exchange word/byte
xlat ! Translate
ol6 ! Operate on a 16 bit object instead of 32 bit
```

#### **Input/Output**

```
in[b] source ! Input from source I/O port
in[b] ! Input from DX I/O port
out[b] dest ! Output to dest I/O port
out[b] ! Output to DX I/O port
```

#### **Address Object**

```
lds reg,source ! Load reg and DS from source
les reg,source ! Load reg and ES from source
lea reg,source ! Load effect address of source to reg and DS
{cdsefg}seg ! Specify seg register for next instruction
al6 ! Use 16 bit addressing mode instead of 32 bit
```

#### **Flag Transfer**

```
lahf ! Load AH from flag register
popf ! Pop flags
pushf ! Push flags
sahf ! Store AH in flag register
```

#### **Addition**

196
197 Control Transfer
198
199    As accepts a number of special jump opcodes that can assemble to
200    instructions with either a byte displacement, which can only reach to
201    targets within -126 to +129 bytes of the branch, or an instruction with
202    a 32-bit displacement. The assembler automatically chooses a byte or
203    word displacement instruction.
204
205    The English translation of the opcodes should be obvious, with
206    'l(ess)' and 'g(reater)' for signed comparisons, and 'b(elow)' and
207    'a(bove)*(CQ for unsigned comparisons. There are lots of synonyms to
208    allow you to write "jump if not that" instead of "jump if this".
209
210    The 'call', 'jmp', and 'ret' instructions can be either
211    intrasegment or intersegment. The intersegment versions are indicated
212    with the suffix 'f'.

266     cmc             ! Complement carry flag
267     stc             ! Set carry flag
268     std             ! Set direction flag
269     sti             ! Set interrupt enable flag
270

```

**Location Counter**

The special symbol '.' is the location counter and its value is the address of the first byte of the instruction in which the symbol appears and can be used in expressions.

**Segments**

There are four different assembly segments: text, rom, data and bss. Segments are declared and selected by the .sect pseudo-op. It is customary to declare all segments at the top of an assembly file like this:

```

283     .sect .text; .sect .rom; .sect .data; .sect .bss
284

```

The assembler accepts up to 16 different segments, but MINIX expects only four to be used. Anything can in principle be assembled into any segment, but the MINIX bss segment may only contain uninitialized data. Note that the '.' symbol refers to the location in the current segment.

```

### Symbol Assignment

Symbols can acquire values in one of two ways. Using a symbol as a label sets it to '.' for the current segment with type relocatable. Alternative, a symbol may be given a name via an assignment of the form

```
symbol = expression
```

in which the symbol is assigned the value and type of its arguments.

### Storage Allocation

Space can be reserved for bytes, words, and longs using pseudo-ops. They take one or more operands, and for each generate a value whose size is a byte, word (2 bytes) or long (4 bytes). For example:

```

389     .data1 2, 6            ! allocate 2 bytes initialized to 2 and 6
390     .data2 3, 0x10         ! allocate 2 words initialized to 3 and 16
391     .data4 010             ! allocate a longword initialized to 8
392     .space 40              ! allocates 40 bytes of zeros
393

```

allocates 50 (decimal) bytes of storage, initializing the first two bytes to 2 and 6, the next two words to 3 and 16, then one longword with value 8 (010 octal), last 40 bytes of zeros.

### String Allocation

The pseudo-ops `.ascii` and `.asciz` take one string argument and generate the ASCII character codes for the letters in the string. The latter automatically terminates the string with a null (0) byte. For example,

```

405     .ascii "hello"
406     .asciz "world\n"
407

```

### Alignment

```

410
411
412
413
414

```

Sep 03, 14 11:21

MAN\_AS.TXT

Page 8/8

```

415
416
417
418

```

Sometimes it is necessary to force the next item to begin at a word, longword or even a 16 byte address boundary. The `.align` pseudo-op zero or more null byte if the current location is a multiple of the argument of `.align`.

### Segment Control

Every item assembled goes in one of the four segments: text, rom, data, or bss. By using the `.sect` pseudo-op with argument `.text`, `.rom`, `.data` or `.bss`, the programmer can force the next items to go in a particular segment.

### External Names

A symbol can be given global scope by including it in a `.define` pseudo-op. Multiple names may be listed, separate by commas. It must be used to export symbols defined in the current program. Names not defined in the current program are treated as "undefined external" automatically, although it is customary to make this explicit with the `.extern` pseudo-op.

### Common

The `.comm` pseudo-op declares storage that can be common to more than one module. There are two arguments: a name and an absolute expression giving the size in bytes of the area named by the symbol. The type of the symbol becomes external. The statement can appear in any segment. If you think this has something to do with FORTRAN, you are right.

### Examples

In the kernel directory, there are several assembly code files that are worth inspecting as examples. However, note that these files, are designed to first be run through the C preprocessor. (The very first character is a # to signal this.) Thus they contain numerous constructs that are not pure assembler. For true assembler examples, compile any C program provided with MINIX using the `-S` flag. This will result in an assembly language file with a suffix with the same name as the C source file, but ending with the `.s` suffix.
